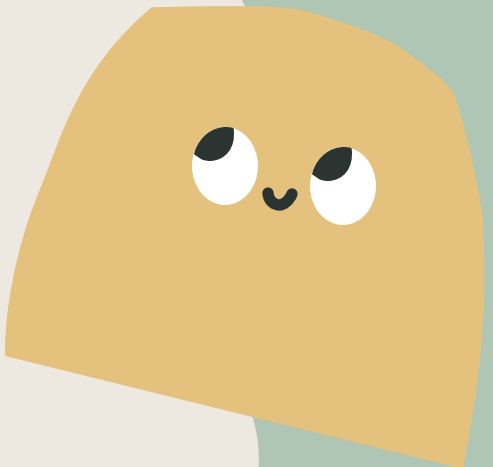
QDAT Sprint 1

10/12/2026



Project Background

- To extract valuable insights from qualitative data, researchers must sift through dozens of pages of survey responses, group discussion transcripts, and interview notes.
- We are aiming to reduce the tedious repetitive work that qualitative data researchers go through and streamline the process of coding whilst maintaining security and anonymity for documents
- The current tools built for this work lag significantly behind large language models (LLMs)
- Unfortunately, LLMs lack the security necessary in this field of work
- Our project aims to provide a solution for this problem by combining a language recognition model with a purpose-built, user-friendly interface to identify codes across multiple documents, report statistics such as code frequency, and cite sources directly.

Overview

- During Sprint 1 our team focused on establishing the foundation for the application.
- We established the GitHub repository through issues and a Kanban board
- We also planned the application architecture to identify the main components and break the project into manageable tasks.
- Initial backend/frontend were created
- This sprint had a few growing pains while we became familiar with the project structure and decided on direction and how our collaboration would look going forward but we think that we established a solid foundation for future work. The goal looking forward is to take the streamlined process we established and continue to integrate more elements inan efficient manner.

Python Backend

- We chose python because of its familiarity and simplicity
- It has a wide range of libraries that can support document processing and data handling
- Frameworks like FastAPI/Flask allow us to create API endpoints to communicate with React frontend
- Python gives us flexibility to expand

React Frontend

- React is simple and familiar and allows us to build the UI in an organized way
- It is a component-based structure so we can break the interface into independently developed pieces
- React can communicate with Python through our API requests
- React just made sense because it can start small but is a scalable foundation for building our project

Building our Starting Point

- Established the backend and frontend as separate parts of the application
- Created the GitHub repository and organized work through issues and a Kanban board
- Planned the architecture and broke the project into manageable tasks
- Worked through initial challenged while becoming familiar with the project structure and team workflow

Kanban Board
